Signature of External

DECLARATION

We hereby declare that this project entitled "**SSH HONEYPOT WITH ML INTEGRATION"** is a bonafide work done by us and submitted to **"Department of Computer Science and Engineering, G. V. P College of Engineering (Autonomous) Visakhapatnam**, in partial fulfilment for the award of the degree of B. Tech is of our own and it is not submitted to any other university or has been published any time before.

PLACE: VISAKHAPATNAM	V. Harshita	(21131A05R5)
DATE:	V. Nirupama Deepthi	(21131A05U1)
	T. Harshita	(21131A05Q5)
	V. Amrutha Varshini	(21131A05R9)

ACKNOWLEDGEMENT

We would like to express our deep sense of gratitude to our esteemed institute **Gayatri Vidya Parishad College of Engineering - (A)**, which has provided us with an opportunity to fulfill our cherished desire.

We express our profound gratitude and our deep indebtedness to our guide **DR. R. VELUMANI Associate Professor** and coordinator **Dr. CH. SITA KUMARI Associate Professor,** Department of Computer Science and Engineering, whose valuable suggestions, guidance and comprehensive assessments helped us a lot in realizing our project successful completion.

We are very thankful to **Dr. C. V. Guru Rao**, **Head of the Department of Computer Science and Engineering, Gayatri Vidya Parishad College of Engineering (Autonomous),** for giving us an opportunity to do the project in college.

We express our sincere thanks to our **Principal Dr. A. B. Koteswara Rao, Gayatri Vidya Parishad College of Engineering (Autonomous)** for his encouragement to us during this project, giving us a chance to explore and learn new technologies in the form of internship.

Finally, I am indebted to the teaching and non-teaching staff of the Computer Science and Engineering Department for all their support in completion of the project.

ABSTRACT

This project presents an advanced cybersecurity solution through a secure and interactive SSH honeypot integrated with machine learning for enhanced threat detection. The honeypot mimics a legitimate SSH server, attracting unauthorized users and logging their commands, credentials, and interactions. These logs are analysed using machine learning to identify behavioural patterns, detect anomalies, and recognize potential threats. By simulating a realistic server environment, it deceives attackers into believing they have gained access, allowing security teams to study their tactics. The system continuously refines its ability to detect malicious activity by learning from past attack data, improving accuracy, reducing false positives, and providing real-time alerts. This honeypot is valuable for cybersecurity, government, and defence sectors, helping organizations proactively detect cyber threats, understand attacker behaviour, and strengthen their security posture. Through the combined power of deception technology and artificial intelligence, this project aims to enhance cybersecurity resilience by offering deep insights into emerging threats and fortifying systems against unauthorized access.

Keywords: Cybersecurity, Threat detection, Behavioural Patterns, Security logs, Machine learning, Unauthorized Access.

1.INTRODUCTION

Cybersecurity and threat detection have become crucial in the modern digital landscape as cyberattacks continue to evolve in complexity and frequency. Organizations must implement robust security measures to protect their systems, networks, and sensitive data from malicious actors who exploit vulnerabilities to gain unauthorized access. One of the most commonly targeted protocols is Secure Shell (SSH), which enables remote system access. Attackers frequently attempt to exploit weak SSH credentials, misconfigurations, or software vulnerabilities to take control of a system. Traditional security mechanisms, such as firewalls and intrusion detection systems, offer some protection but often struggle to detect sophisticated or evolving attack techniques. This limitation underscores the necessity of advanced security strategies, such as deception-based security and machine learning-driven threat detection.

Deceptive security systems, like SSH honeypots, are instrumental in understanding attacker behaviour. These systems mimic real servers, tricking attackers into engaging with them and revealing their strategies, tools, and techniques. By monitoring and logging these interactions, security teams can analyse attack patterns and develop more effective countermeasures. However, manually analysing large volumes of attack data can be time-consuming and inefficient. This is where machine learning plays a critical role in threat detection.

Machine learning enhances security by automatically processing vast amounts of data collected from attacker interactions, including login attempts, commands, and system responses. It identifies patterns, detects anomalies, and recognizes potentially malicious behaviour in real time. Unlike traditional rule-based security systems, machine learning continuously learns from new data, adapting to emerging threats and improving its predictive capabilities. This dynamic approach reduces response times, minimizes false positives, and strengthens overall cybersecurity resilience. By integrating machine learning with cybersecurity, organizations can proactively detect, analyse, and mitigate threats, ensuring a more adaptive and robust security posture. Ultimately, the combination of deception technology and artificial intelligence empowers organizations to stay ahead of cybercriminals and fortify their defences against evolving cyber threats.

1.1 Objective

The primary objective of this project is to develop an SSH honeypot integrated with machine learning to detect, analyse, and understand unauthorized access attempts. The system aims to simulate a real SSH server, attracting attackers while capturing their activities for threat intelligence. By leveraging deception-based security, the honeypot records login attempts, executed commands, and behavioural patterns, allowing security teams to analyse malicious activities in real time. Furthermore, the project seeks to integrate machine learning models to automatically detect anomalies, recognize attack patterns, and enhance cybersecurity defences.

1.2 Purpose

This project is designed to address the limitations of traditional security measures that struggle to detect sophisticated cyberattacks. Firewalls and intrusion detection systems provide basic protection, but they often fail to identify evolving attack techniques. By implementing a deceptive security system, organizations can lure attackers into interacting with a controlled environment, preventing them from reaching critical systems. Additionally, machine learning enhances the system by automating the detection of suspicious behaviour, reducing false positives, and enabling real-time threat analysis. The purpose of this project is to provide a proactive security solution that strengthens organizational resilience against cyber threats.

1.3 Scope

The scope of this project extends to various cybersecurity applications, including network security, government, and enterprise defence systems. The SSH honeypot can be deployed in corporate environments, research institutions, and cybersecurity firms to monitor and analyse attacker behaviour. The machine learning integration enables continuous improvement, ensuring that the system adapts to new threats and enhances predictive capabilities. Additionally, the collected data can be used for forensic analysis, cybersecurity training, and future threat intelligence development. This project contributes to the advancement of cybersecurity measures by combining deception technology, AI-driven analysis, and real-time threat detection to safeguard critical systems from unauthorized access.

2. LITERATURE SURVEY

SSH honeypots are becoming a valuable tool in cybersecurity, helping to trap hackers and study their behaviour. They act like real SSH servers, tricking attackers into revealing their methods while keeping actual systems safe. With machine learning, these honeypots can spot patterns, detect suspicious activity, and improve threat detection over time. This makes them a powerful way to boost security and stay ahead of cyber threats.

2.1 Previous Papers

Warren Z. Cabral, Craig Valli, Leslie, F. Sikos, Samuel, G. Wakeling authored the paper **"Advanced Cowrie Configuration to Increase Honeypot Deceptiveness"**. Cowrie is a medium-interaction SSH and Telnet honeypot that logs brute-force attacks and SSH requests, but its publicly available code makes it vulnerable to detection. Most deployments use default configurations, making them easier for attackers to identify using tools like NMAP and Shodan. This research proposes a customizable framework to enhance Cowrie's deception and realism, comparing default and modified setups to evaluate effectiveness.

Sajeel Mehta, Dipti Pawade, Yash Nayyar, Ashwini Dalvi wrote the paper **"Cowrie Honeypot Data Analysis and Predicting the Directory Traverser Pattern of Attack".** Cowrie Honeypot is used to entrap intruders, log their activities, and analyse their behaviour to enhance security. Logged data is processed and visualized using ELK, helping identify attack patterns. Additionally, a probabilistic approach predicts intruder directory traversal patterns, enabling proactive security measures.

Vasu Sethia, A Jeyasekar authored the paper **"Malware Capturing and Analysis using Dionaea Honeypot"**. The rapid growth of the internet has led to increased cyber threats, including malware, spyware, and botnets that steal sensitive data and cause harm. This study deploys a honeypot to capture zero-day attacks and analyse network logs to classify malware based on behaviour. These insights help researchers develop security mechanisms to protect organizations from malicious activities.

Melike Baser, Ebu Yusuf Guven; Muhammed Ali Aydın authored the paper **"SSH and Telnet Protocols Attack Analysis Using Honeypot Technique: Analysis of SSH and Telnet Honeypot".** Traditional cybersecurity measures often fail against zero-day attacks, making honeypots essential for recording attacker behaviour and developing new defence strategies. This study deploys an SSH-Telnet honeypot using Cowrie to log attacker activities and analyse threats. Collected data, including logs and uploaded files, is shared on GitHub to aid further research.

Christoph Pohl, Alf Zugenmaier, Michael Meier & Hans-Joachim Hof wrote the paper "**B. Hive: A Zero Configuration Forms Honeypot for Productive Web Applications".** Honeypots detect intrusions by attracting attackers and logging their actions for analysis, aiming to remain undetected while appearing valuable. This paper introduces B. Hive, a novel honeypot that protects active web applications while concealing its presence from detection. B. Hive requires no configuration changes, is web framework agnostic, and has minimal impact on performance, making it effective for protecting top websites.

2.1 Objectives of the Literature Survey

The primary objective of this literature survey is to explore and analyse existing research on honeypots, particularly SSH and Telnet honeypots, to identify their strengths, weaknesses, and potential areas for improvement. However, traditional honeypots have limitations, such as detectability and lack of intelligent threat analysis. This survey aims to gather insights from existing studies to develop a more advanced and deceptive honeypot system.

Objectives

- Understanding Existing Honeypot Technologies
- Identifying Security Gaps
- Exploring Machine Learning in Threat Detection
- Analysing Attack Trends and Intruder Behaviour
- Developing an Optimized Honeypot Framework

This literature survey serves as a foundation for designing a more effective honeypot that overcomes the limitations of traditional systems. By integrating machine learning, improving deception techniques, and addressing security gaps, an optimized honeypot can provide enhanced cybersecurity measures. The findings from this study will contribute to the development of a robust honeypot system that can effectively monitor, analyse, and respond to evolving cyber threats.

3. EXISTING SYSTEMS

3.1 Methodology

Dionaea Honeypot for Malware Capture

- Emulates vulnerable network services like SMB, FTP, HTTP, and MySQL to attract attackers.
- Logs network traffic, collects malware samples, and records attacker interactions.
- Supports automated malware submission for deeper cybersecurity analysis.
- Helps in identifying new attack vectors and studying malware behaviour.

Cowrie Honeypot for SSH & Telnet Attack Monitoring

- Simulates a real SSH/Telnet server to capture brute-force attack attempts.
- Logs credentials, executed commands, and session activities for analysis.
- Integrates with ELK (Elasticsearch, Logstash, Kibana) for real-time monitoring.
- Enhances deception by allowing attackers to believe they have accessed a real system**.**

Kippo Honeypot for SSH Attack Analysis

- Focuses on studying SSH brute-force attacks by allowing attackers to log in with weak credentials.
- Captures login attempts, command execution, and session activities.
- Provides detailed logs to reconstruct attack scenarios for forensic analysis.
- Although outdated, its successor, Cowrie, builds upon its functionality with improved features.

T-Pot: Multi-Honeypot Threat Intelligence System

- Combines multiple honeypots (Cowrie, Dionaea, Glastopf, Conpot) into a unified system.
- Monitors threats across various attack vectors, including SSH, web applications, and industrial systems.
- Offers built-in visualization tools like ELK for real-time data analysis.
- Used for large-scale cybersecurity **research and enterprise-level threat monitoring.**

Honeyd for Network Emulation and Attack Logging

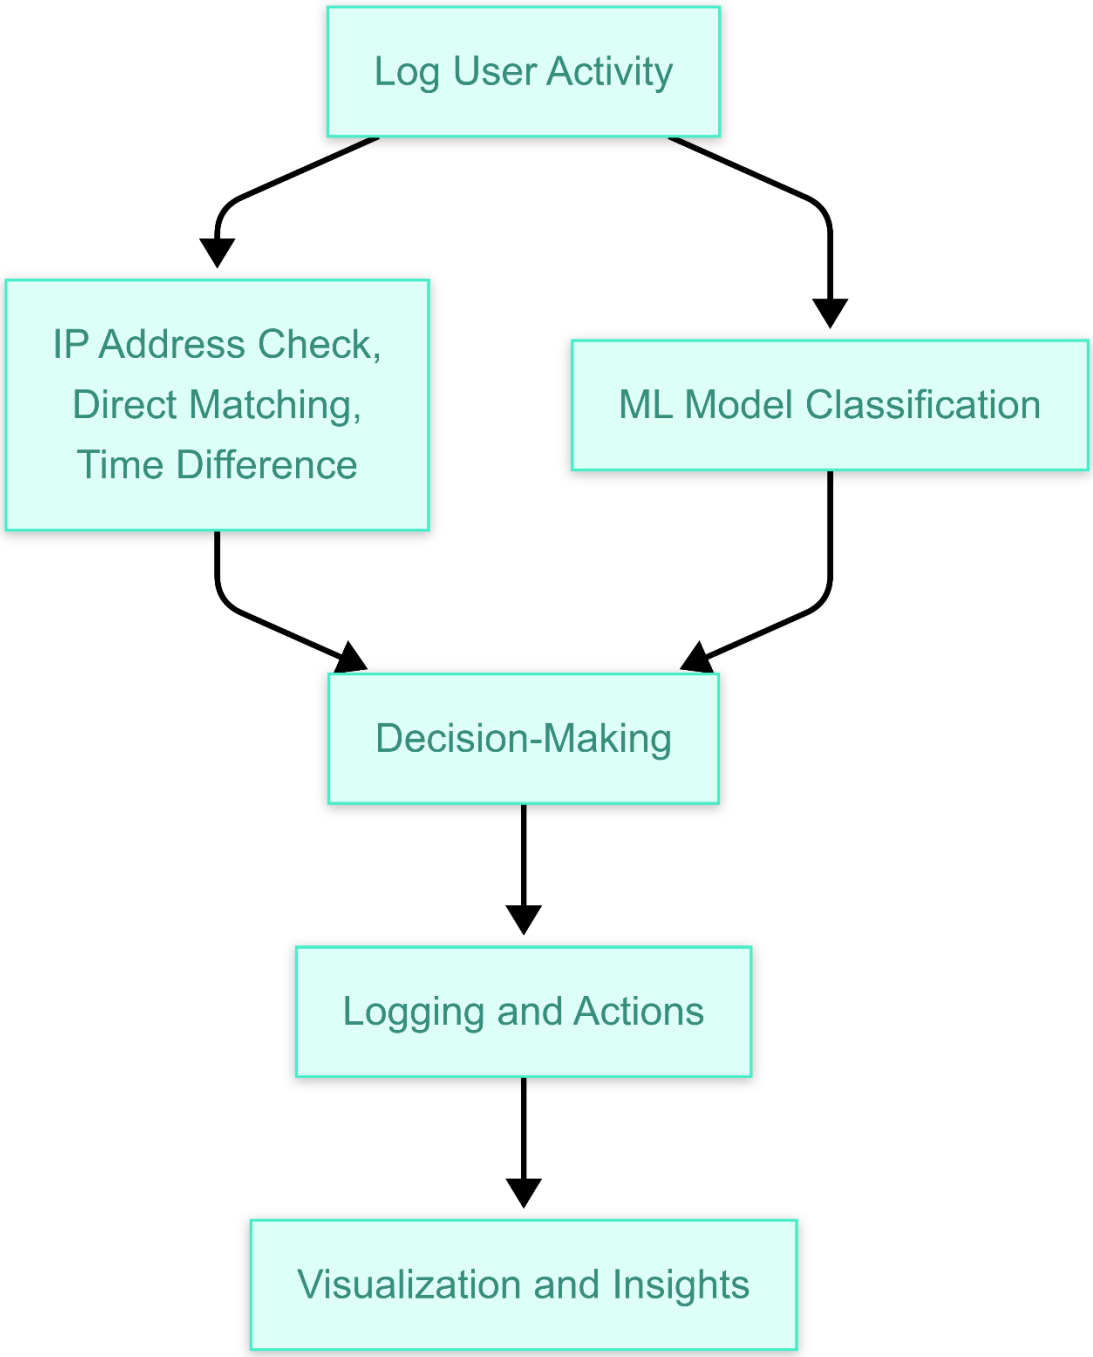
- Creates virtual hosts to mimic different operating systems and services.
- Simulates network vulnerabilities to study attack methodologies.
- Captures network scanning, fingerprinting, and unauthorized access attempts.
- Useful for detecting **attacker behaviors and strengthening network security.**

3.2 Drawbacks

- **Limited Attack Interaction:** As a low-interaction honeypot, it may not fully capture complex, multi-step attack scenarios or advanced persistent threats (APTs).
- **Accuracy Concerns:** While machine learning enhances detection, anomalies in attacker behaviour may lead to false positives or missed threats.
- **Resource Intensity:** Running machine learning models for real-time analysis requires significant computational power, which may limit deployment on low-resource systems.
- **Potential Detection by Attackers:** Skilled attackers may recognize the honeypot environment, avoiding interaction or using evasion techniques to bypass logging.
- **Data Privacy Challenges:** Storing and analysing attacker logs involves handling sensitive data, requiring strict security measures to prevent misuse or leaks.
- **No Machine Learning:** It does not use ML models to detect patterns or predict behaviours based on logs.
- **Command Analysis:** Primarily focused on malware rather than interactive attacker behaviour like SSH commands.

4.PROPOSED SYSTEM

4.1 Block Diagram



4.2 Modules

1.SSH Honeypot Simulation

This module sets up a deceptive SSH server using the Cowrie honeypot to attract attackers and log their activities. It records login attempts, executed commands, and uploaded files, providing valuable insights into attacker behaviour. The honeypot mimics a real SSH environment, ensuring high interaction levels while maintaining security and deception.

2.Intruder Activity Logging & Analysis

All interactions with the SSH honeypot are logged in real-time, capturing credentials, session details, and executed commands. The collected logs are structured and preprocessed using log parsing algorithms. The processed data is then analysed for anomaly detection and behavioural pattern recognition.

3.Machine Learning-Based Threat Detection

This module integrates Isolation Forest and TF-IDF vectorization to detect unusual patterns in attacker behaviour. Machine learning techniques help classify login attempts as legitimate or malicious and identify frequently used attack commands. This enhances proactive threat detection and intrusion response.

4.Data Visualization & Reporting

Attack trends and intruder behaviour are visualized using tools like ELK Stack, Matplotlib, and NetworkX. Graphical representations include command flow graphs, heatmaps of login attempts, and statistical summaries of attack patterns. This helps cybersecurity researchers and system administrators understand emerging threats and take preventive measures

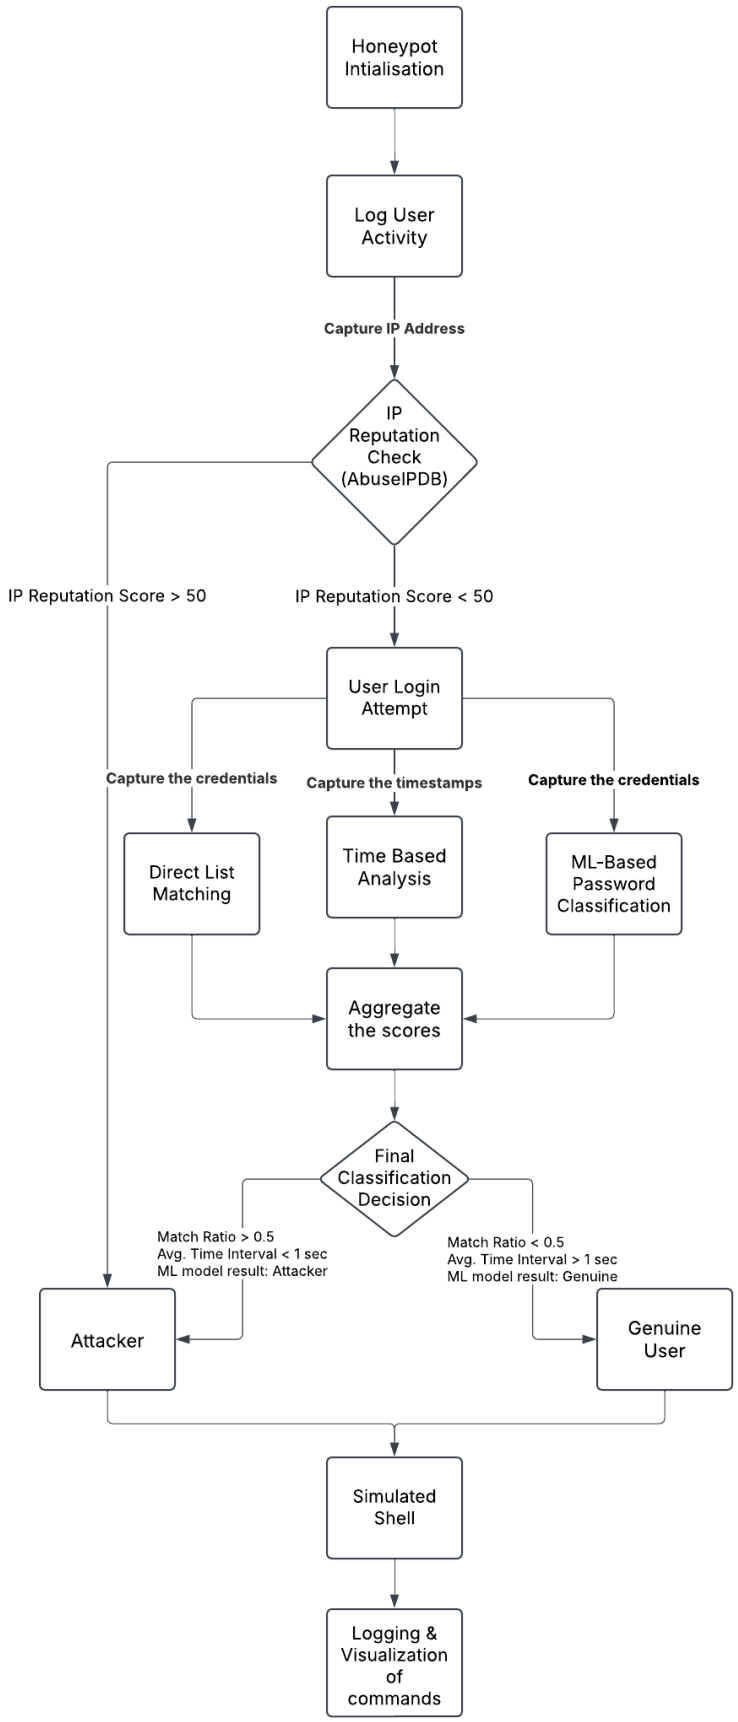
5.Automated Alert System

This module enhances real-time monitoring by sending alerts when suspicious activity is detected. Using Socket and Threading, it continuously monitors incoming connections and triggers alerts via email or Telegram APIs when predefined attack thresholds are met.

6.Custom Honeypot Configuration & Deployment

To improve deception, this module allows security professionals to modify the SSH honeypot configuration dynamically. Unlike default Cowrie setups, it offers customizable environments that make detection harder for attackers using NMAP or Shodan scans. The honeypot can be deployed on virtual machines or cloud platforms for scalable cybersecurity research.

4.3 Flow Diagram



4.4 Methodology

Classification of Attackers

In cybersecurity, identifying and categorizing attackers is crucial for preventing unauthorized access and strengthening security. Our project classifies attackers based on multiple factors, such as IP addresses, login attempts, timestamps, and behavioural patterns detected using machine learning. By analysing these elements, we can recognize different attack strategies, detect brute force attempts, and predict malicious activities more effectively.

Below are the key steps involved in attacker classification:

1.IP Address Tracking

The first step in attacker classification is tracking the IP address of every login attempt. This helps in identifying repeated attack sources and determining whether an attack is coming from a specific region or a widely distributed botnet. If the same IP is involved in multiple unauthorized access attempts, it can be flagged as suspicious. Additionally, IP-based classification allows for preventive measures such as blacklisting, blocking known malicious IPs, and monitoring attack trends to understand their origin and scale.

2. Brute Force Detection

One of the most common attack techniques is brute force, where attackers use automated tools to guess valid SSH credentials. Our system detects brute force attempts by monitoring login failures, particularly when an IP makes seven consecutive unsuccessful attempts. If this threshold is reached, the system classifies the activity as a brute force attack. This direct match approach helps in identifying aggressive attackers and distinguishing them from legitimate users who may have simply mistyped their credentials. Once detected, such attackers can be logged, flagged, or even automatically blocked to prevent further intrusion attempts.

3. Timestamp Analysis

Every interaction with the SSH server is recorded along with a precise timestamp, which provides insights into attack patterns. By analysing timestamps, we can detect how frequently an attacker is attempting to gain access. If a large number of login attempts occur within a short period, it indicates a high-intensity attack. On the other hand, some attackers use slow brute force techniques, spreading their attempts over hours or even days to avoid detection. By studying the timestamps, we can classify attackers based on their approach and respond accordingly, either by flagging, blocking, or adjusting security measures.

4. Machine Learning-Based Pattern Detection

While IP tracking, brute force detection, and timestamp analysis provide effective rule-based classification, attackers continuously evolve their techniques. To overcome this, we integrate a machine learning model that detects patterns beyond direct rule-based detection. The model analyses past attack data to recognize behavioural similarities, even when attackers change IPs or slightly modify their attack strategies. Over time, this allows for dynamic learning, where the system adapts to new threats without needing manual rule updates. As the ML model improves, it enhances proactive security by identifying potential threats before they become widespread, making the system more resilient to emerging cyber threats.

4.5 Performance Measure

To evaluate the effectiveness and efficiency of our SSH honeypot system, we establish key performance indicators (KPIs) focusing on attack detection accuracy, system performance, deception effectiveness, and data analysis capabilities. These measures ensure that the honeypot remains undetectable while capturing valuable cyber threat intelligence.

1. Intrusion Detection & Logging Efficiency

To assess how effectively the honeypot captures and logs attacker activities:

- Attack Detection Rate: Successfully identifying at least 95% of intrusion attempts.
- Log Completeness: Ensuring that 100% of login attempts and commands are recorded.
- Missed Attacks: Keeping undetected intrusion attempts below 5%.
- Time to Log Events: Logging attack data within 500ms for real-time monitoring.

2. Machine Learning Accuracy & Threat Classification

- To measure the system's ability to analyse and classify attack behaviours:
- Anomaly Detection Accuracy: Achieving at least 90% accuracy in identifying suspicious activity.
- False Positive Rate: Keeping incorrect threat classifications below 5%.
- Attack Pattern Recognition: Correctly clustering at least 85% of command sequences using TF-IDF and Isolation Forest.
- Real-Time Behaviour Analysis: Processing attacker commands and updating ML models within 2 seconds.

3. System Performance & Scalability

To maintain a stable and high-performing honeypot environment:

- System Uptime: Ensuring 99.9% availability for uninterrupted attack logging.
- Latency: Keeping honeypot response times under 1 second for seamless interaction with attackers.

- Log Storage & Retrieval Time: Retrieving stored attack logs within 300ms for real-time analysis.
- Concurrent Session Handling: Supporting at least 100 simultaneous attacker sessions without performance degradation.

4. Deception Effectiveness & Honeypot Undetectability

To ensure the honeypot remains disguised as a real system:

- Fingerprinting Resistance: Preventing detection by tools like NMAP and Shodan in at least 95% of scans.
- Session Duration: Keeping attackers engaged for at least 10 minutes per session to collect more data.
- Credential Success Rate: Using realistic fake credentials that attackers attempt to use at least 80% of the time.
- Command Interaction Complexity: Ensuring attackers execute a variety of commands, not just automated scripts.

5. Data Analysis & Visualization Effectiveness

To measure how well attack data is processed and presented:

- Visualization Clarity: Providing graphical attack trends with at least 90% accuracy in representing data.
- Anomaly Trend Insights: Detecting and categorizing new attack techniques within 24 hours.
- Report Generation Speed: Producing detailed security reports within 5 seconds.
- Threat Intelligence Sharing: Ensuring processed data can be exported for cybersecurity research and forensic analysis.

These performance measures ensure our SSH honeypot remains an effective tool for cybersecurity research and threat intelligence gathering. By maintaining high intrusion detection rates, deception capabilities, and system stability, the honeypot can efficiently log attacker behaviours while remaining undetectable. Continuous machine learning updates and visualization tools further enhance the system's ability to analyze and respond to evolving cyber threats.

4.6 Advantage

1. Smart Threat Detection with Machine Learning

- Uses Isolation Forest to detect unusual login attempts and brute force attacks.
- Learns from new attack data over time, improving accuracy.
- Reduces the risk of undetected threats by identifying suspicious activities early.

2. Detailed Attack Data Collection

- Logs IP addresses, login attempts, command sequences, and timestamps.
- Provides in-depth insights into attacker behaviour for forensic analysis.
- Captures more detailed **data compared to basic honeypots like Cowrie.**

3. Easy-to-Understand Visual Reports

- Uses bar charts, word clouds, and graphs to display attack patterns.
- Helps security analysts quickly identify common attack techniques.
- Makes it easier to spot unusual **access routes and frequently used commands.**

4. Adapts to New Attack Methods

- Continuously updates itself with new attack patterns.
- Detects emerging threats like credential stuffing and automated scripts.
- Evolves with the changing cybersecurity landscape for long-term protection.

5. Efficient and Scalable

- Works on low-cost hardware or virtual machines with minimal resources.
- Supports multi-threading to handle multiple SSH connections at once.
- Ideal for large-scale security monitoring while keeping costs low.

6. Highly Accurate Detection

- Uses machine learning to distinguish between real threats and normal activity.
- Reduces false positives, ensuring legitimate users are not mistakenly flagged.
- Improves over time by adjusting detection thresholds based on data.

7. Proactive Security Measures

- Detects and classifies attacks in real-time, providing early warnings.
- Enables organizations to respond quickly to suspicious activity.
- Goes beyond passive monitoring by actively identifying attack patterns.

8. Automated and User-Friendly

- Uses regular expressions (regex) to automatically clean and process logs.
- Transforms raw data into structured formats for easy machine learning analysis.
- Can be integrated with SIEM platforms for real-time security monitoring.
- This system makes cybersecurity monitoring smarter, faster, and easier while providing detailed insights into hacker behaviour.

5. DATASET AND ALGORITHM

5.1 Dataset

Our SSH honeypot project utilizes two primary datasets:

- Attack Log Dataset
- Machine Learning Dataset

1. Attack Log Dataset

This dataset captures real-time intrusion attempts, logging attacker behaviours and patterns. It helps analyse threats, detect anomalies, and improve cybersecurity defences.

- Intrusion Attempts: Logs failed and successful SSH login attempts.
- Command Execution History: Records all commands entered by attackers.
- Brute Force Data: Stores commonly attempted usernames and passwords.
- Malware Uploads: Logs files uploaded to the honeypot for further analysis.
- Geolocation Information: Tracks attacker IP addresses, ISPs, and countries.
- Time-Based Trends: Identifies peak attack hours and long-term attack trends.

2. Machine Learning Dataset

- This dataset is used to train models for detecting malicious activities and classifying attacks.
- Attack Signatures: Categorizes login attempts as brute force, privilege escalation, or reconnaissance.
- Command Frequency Patterns: Identifies commonly used attack commands.
- Anomaly Scores: Uses machine learning models like Isolation Forest for anomaly detection.
- Session Duration Metrics: Tracks how long an attacker interacts with the honeypot.
- Network Traffic Data: Captures SSH packets for deep behavioural analysis.
- Threat Intelligence Integration: Cross-references known malicious IPs and attack patterns from external sources.

These datasets enable comprehensive threat detection, behaviour analysis, and machine learning-driven attack classification. By continuously updating and refining the dataset, the honeypot system remains adaptive to emerging cyber threats.

5.2 Algorithm

Log Parsing, Machine Learning, and Visualization Techniques

Our SSH honeypot system processes raw intrusion logs, applies machine learning-based anomaly detection, and visualizes attack behaviours to gain deeper cybersecurity insights. Below is a detailed breakdown of the key techniques used:

1. Log Parsing & Preprocessing

Before performing analysis, raw SSH logs from the honeypot need to be structured and cleaned.

Log Parsing Algorithm:

- Extracts key fields such as timestamps, attacker IPs, usernames, attempted passwords, command sequences, and session durations.
- Filters out irrelevant system logs, keeping only malicious activity data for efficient processing.

Data Preprocessing Techniques:

- Label Encoding: Converts categorical data (e.g., usernames, attack types) into numerical form to facilitate machine learning analysis.
- Standardization: Uses Standard Scaler to normalize features (e.g., session duration, command frequency) to a mean of 0 and variance of 1, improving model stability.

2. Machine Learning-Based Anomaly Detection

To identify malicious SSH activities, the system applies anomaly detection techniques.

Isolation Forest Algorithm:

- Trains on normal SSH command patterns to detect deviations in attacker behaviour.
- Flags suspicious login attempts, unknown commands, or privilege escalation attempts as outliers.

Supervised Learning (Optional):

- If labelled data is available, models like Random Forest, XGBoost, or SVM can be used to classify attack types (brute force, reconnaissance, or malware execution).
- Helps in predicting whether an attacker is a bot or a human based on behaviour patterns.

3. Attack Pattern Recognition & Visualization

To better understand attacker strategies, the system visualizes data using text mining and graph-based techniques.

- TF-IDF (Term Frequency - Inverse Document Frequency):
- Analyses the most frequently used SSH commands by attackers.
- Identifies rare or unique commands executed by sophisticated hackers.

Results are visualized using:

- Bar charts – Displays top commands used by attackers.
- Word clouds – Highlights most common commands visually.
- Histograms – Shows frequency distributions of attack attempts over time.

Graph Theory (Network Analysis):

- Nodes represent individual commands, while edges represent transitions between them.
- Helps visualize how attackers navigate through the system, whether they are exploring directories, modifying files, or escalating privileges.
- Implemented using NetworkX and Matplotlib to generate attack flow graphs.

Hardware & Software Requirements

Hardware Requirements

To efficiently run the SSH honeypot, analyse attack data, and process machine learning models, the following hardware setup is recommended:

Minimum Requirements:

1. Processor: Intel Core i3 or equivalent (basic logging & ML processing).
2. RAM: 4GB (sufficient for small-scale honeypot deployments).
3. Storage: 20GB HDD (for storing SSH logs and attack data).
4. Network: Stable internet connection (for SSH interactions and attack logging).

Recommended Requirements:

- Processor: Intel Core i5/i7 or AMD Ryzen 5/7 (for faster machine learning processing).
- RAM: 8GB or more (for handling large-scale attack data).
- Storage: 50GB+ SSD (for fast log storage, retrieval, and visualization processing).
- Optional GPU: NVIDIA GPU (if deep learning models are required for advanced classification).
- Server Deployment: Virtual machine or cloud-based instance (AWS, Azure, GCP) for scalable security research.

Software Requirements

A combination of security tools, machine learning frameworks, and visualization libraries are needed to deploy and analyse the honeypot system**.**

Operating System:

1. Preferred: Kali Linux (includes built-in security tools).
2. Alternative: Ubuntu 20.04+ (lightweight and customizable for honeypot deployment).
3. Testing Environment: Windows (optional, for data analysis and visualization).

Programming Language:

Python 3.11+ – Used for honeypot setup, log parsing, machine learning, and visualization.

Libraries & Packages:

- Paramiko: Simulates SSH connections and records login attempts.
- Scikit-learn: Implements Isolation Forest for anomaly detection.
- Pandas & NumPy: Handles log preprocessing, feature extraction, and data storage.
- Matplotlib & Seaborn: Creates bar charts, histograms, and heatmaps for attack analysis.
- NetworkX: Generates graph-based attack flow visualizations.
- Pickle/Joblib: Saves and loads machine learning models efficiently.
- Socket & Threading: Enables real-time monitoring of SSH connections.
- Regex (re module): Extracts specific attack patterns from log files.
- ELK Stack (Elasticsearch, Logstash, Kibana) (Optional): Used for interactive log visualization.

Visualization Tools:

- Matplotlib & Seaborn – Plots command execution trends and attacker activity.
- Gephi (Optional) – Creates interactive network graphs to analyse SSH attack flows**.**

By combining log parsing, machine learning-based threat detection, graph-based attack analysis, and visualization techniques, our SSH honeypot provides deep insights into attacker behaviour. The hardware and software stack ensures smooth performance, real-time monitoring, and high-quality security analytics.

8. TESTING

8.1 INTRODUCTION TO TESTING

Software Testing is defined as an activity to check whether the actual results match the expected results and to ensure that the software system is Defect free. It involves the execution of a software component or system component to evaluate one or more properties of interest. It is required for evaluating the system. This phase is the critical phase of software quality assurance and presents the ultimate view of coding.

Importance of Testing

The importance of software testing is imperative. A lot of times this process is skipped, therefore, the product and business might suffer. To understand the importance of testing, here are some key points to explain

- Software Testing saves money
- Provides Security
- Improves Product Quality
- Customer satisfaction

Testing is of different ways the main idea behind the testing is to reduce the errors and doit with a minimum time and effort.

Benefits of Testing

- *Cost-Effective:* It is one of the important advantages of software testing. Testing any IT project on time helps you to save your money for the long term. In case if the bugs caught in the earlier stage of software testing, it costs less to fix.

- *Security:* It is the most vulnerable and sensitive benefit of software testing. People are looking for trusted products. It helps in removing risks and problems earlier.

- *Product quality:* It is an essential requirement of any software product. Testing ensures a quality product is delivered to customers

- *Customer Satisfaction:* The main aim of any product is to give satisfaction to their customers. UI/UX Testing ensures the best user experience.

8.2 Unit Testing

During the testing phase, we conducted extensive evaluations to ensure the accuracy and reliability of our SSH Honeypot with ML integration.

1. **Honeypot Data Collection Validation:**

   We simulated multiple unauthorized login attempts using known weak passwords and complex patterns.

   The system successfully captured and logged all login attempts, including timestamps, IP addresses, and commands executed by the attacker.

2. **Machine Learning Model Accuracy Testing:**

   The Isolation Forest model was tested with both benign and malicious login attempts.

   The model consistently identified suspicious patterns, correctly classifying anomalous activities with high precision.

   We validated the classification results by comparing them with manually labeled attack patterns.

3. **Log Parsing and Data Preprocessing:**

   To ensure proper feature extraction, we tested our log parsing algorithm on diverse datasets.

   The LabelEncoder and StandardScaler successfully transformed categorical and numerical features without errors.

   The TF-IDF technique correctly identified frequently used SSH commands from the attack logs.

4. **System Performance and Stress Testing:**

   We simulated multiple simultaneous SSH connections to test system stability.

   The honeypot efficiently handled concurrent connections, with logs being stored correctly.

   The threading mechanism prevented system crashes under heavy load.

5. **Visualization and Report Generation:**

   We validated data visualization outputs using sample attack datasets.

   Graph-based network analysis accurately represented attacker command flows.

The honeypot correctly generated interactive heatmaps, word clouds, and bar charts for security insights.

6. **Final Testing and Debugging:**

   The entire system was run through 20 test cases involving different attack patterns, botnet attempts, and manual penetration testing.

   Each component performed as expected, with no critical failures detected.

   These tests confirmed the effectiveness of our SSH honeypot and its machine-learning integration in identifying and analyzing unauthorized access attempts.

9. CONCLUSION

Our SSH honeypot system provides an advanced cybersecurity solution by combining machine learning, real-time monitoring, and detailed attack analysis. Unlike traditional honeypots, which rely solely on static logging, this system enhances threat detection, attacker behaviour analysis, and proactive security measures. By leveraging Isolation Forest for anomaly detection, TF-IDF for attack pattern recognition, and graph theory for command flow visualization, the honeypot efficiently identifies suspicious activities and provides meaningful insights into evolving cyber threats. The system's adaptive learning ensures it continuously improves, making it highly effective against emerging attack strategies like credential stuffing, automated scripts, and brute force attacks. Additionally, the system is designed for scalability and efficiency, capable of running on minimal hardware resources while supporting large-scale deployments. Its automated log parsing, real-time alerts, and SIEM integration make it a user-friendly and proactive cybersecurity tool for organizations seeking to strengthen their network defences.

Overall, this project enhances cybersecurity by providing real-time threat intelligence, improving attack detection accuracy, and reducing response time to security incidents. By continuously evolving, the system remains a powerful tool for preventing, detecting, and analysing SSH-based attacks in modern cybersecurity landscapes

10.FUTURE SCOPE

As cyber threats become more advanced, the future scope of this SSH honeypot system lies in enhancing its intelligence, adaptability, and scalability. One major improvement would be the integration of deep learning models, such as Long Short-Term Memory (LSTM) networks or Transformer-based architectures, to analyse attack behaviours more accurately. These models could help differentiate between human attackers, automated scripts, and botnets, further refining intrusion detection. Additionally, expanding the honeypot to support multiple protocols, including Telnet, RDP, and FTP, would make it a more comprehensive security tool capable of monitoring various attack vectors beyond SSH.

Another key advancement would be the integration of real-time threat intelligence feeds from sources like AbuseIPDB and VirusTotal, allowing the system to cross-reference attacker IPs and proactively blacklist known malicious entities. Automated incident response mechanisms could also be implemented, enabling the honeypot to dynamically alter its behaviour based on attacker interactions or redirect threats to isolated environments for further study. This would transition the system from a passive logging tool to an active defence mechanism capable of misleading and studying adversaries in real-time.

To enhance usability and accessibility, cloud-based deployment on platforms like AWS, Azure, or Google Cloud could allow for scalable and distributed honeypot implementations. This would enable security teams to monitor global attack trends and improve detection across different network environments. Furthermore, improving data visualization with interactive dashboards, real-time attack heatmaps, and AI-powered risk assessments would provide deeper insights for security analysts, making it easier to track and understand attacker behaviours.

Overall, the future of this SSH honeypot system lies in continuous learning, automated threat mitigation, and expanded protocol support. By integrating advanced AI, cloud scalability, and real-time analytics, the system can evolve into a powerful cybersecurity tool capable of detecting, analysing, and preventing sophisticated cyberattacks in real-world environments.

11. USER MANUAL

1) First the user can dump the IP address using tcp dump command and can randomly try connecting our Honeypot

2) User scans for open SSH ports using tools like Nmap:

- **nmap -p 22 <honeypot_IP>**

3) If users connect the Honeypot through Linux or similar environments The user (attacker or legitimate user) connects using SSH:

- **ssh username@<honeypot_IP>**
- Our honeypot asks for a password, just like a real SSH server:

  password:

- The entered username and password are captured for logging and analysis.

4) Based on the classification made by the system, the honeypot simulates a shell like

environment

5) Logging and Monitoring

- Every login attempt, command execution, and suspicious behaviour is logged.
- We record:
  - Username & Password entered
  - IP Address of the user
  - Commands executed
  - Time of login & session duration
